Abstract

Emerging contaminant in drinking water has created concerns among public, water supplier and government. Pharmaceutical in water and food even in low concentration have shown potential risks to human. Acetaminophen and ibuprofen are among a set of the most prescribed drugs in the world. In this study raw water and treated drinking water from Latyan drinking water treatment facilities were analyzed to determine possible concentration of acetaminophen and ibuprofen in water. All the data were subjected to analysis of variance to consider significance of differences. Furthermore mean comparison between data was calculated using Duncan test. Presence of acetaminophen in the ground water resources was not reported. While in the Jajrood river and Latyan Dam Lake the concentration of acetaminophen were 2.16 ± 0.09 and 9.17 ± 0.18 ηg L^{-1} respectively. In the case of ibuprofen the only observed concentration was equal to 11.49 ± 0.33 in the Latyan Dam Lake. No concentration of acetaminophen and ibuprofen was detected in drinking water samples gathered after treatment process.Why pharmaceuticals were known as indicators for controlling the quality of raw water and the treatment efficiency in the drinking water treatment facilities, ground water and treated water of this area are safe with no detection of acetaminophen and ibuprofen.

Keywords: Raw water, Acetaminophen, Ibuprofen, Contamination.

Introduction

Pharmaceutical compounds enter to the environment via discharge of treated wastewater, septic tanks, landfills, sewer lines, animal waste runoff and manure fertilizers (Fram & Belitz 2011). Many of these pharmaceuticals have been recognized to survive in wastewater treatment and be discharged to surface and groundwater.

Moreover pharmaceutical in drinking water has created concerns among public, water supplier and govĕrnment. Pharmaceutical in water and food even in low concentration have shown potential risks to human. Emission of pollutants from sewage to drinking water increased risk of cancers in human (Luque-Espinar, Navas, Chica-Olmo, Cantarero-Malagón & Chica-Rivas 2015). In many countries occurrence and fate of pharmaceutical in raw water and in food products remains unknown. However the presence of this pollutants and their by-product in drinking water must be considered even where their concentrations are very low (Mompelat, Le Bot & Thomas (2009); Caban, Lis, Kumirska & Stepnowski, (2015)). Moreover from many aspects, pharmaceutical pollution of drinking water can be considered. Disinfection of drinking water in treatment process produce byproducts which have been proven to be more toxic than their parent compounds. Postigo & Richardson (2014) and Fram & Belitz (2011) have reported that concentration of pharmaceutical compound in wastewater after treatment process are less than 1 μg L^{-1} while in many cases pharmaceutical concentrations are detected about several mg L^{-1} specially in effluent from treatment facilities that receive waste from pharmaceutical manufacturing (Phillips, Smith, Kolpin, Zaugg, Buxton & Furlong, (2010); Fram & Belitz (2011)) . In the study carried out by Padhye, Yao, Kung'u & Huang (2014) average total pharmaceutical and personal care products and endocrine disrupting chemicals concentration in the surface water source was around 360 ng L^{-1} . Furthermore In the study carried out by Lin, Yu & Chen (2016) after a series of treatment processes, indomethacin, caffeine and sulfamethoxazole were found in effluent, at concentrations less than 2 ng L^{-1} Luque-Espinar *et al.* (2015) have found that the concentration of paracetamol in rivers and channels was up to 34.3 μg L^{-1}. Because most of the drinking water treatment facillities all over the world are not specifically designed to remove pharmaceutical active compounds, thereby these compounds are found in drinking water (Vergili 2013). There are presently no regulations or drinking water directives for pharmaceutical products. Rosal, Antonio Rodríguez, Perdigón-Melón, Petre, García-Calvo, José Gómez, Agüera, Amadeo &Fernández-Alba (2010) have reported that acetaminophen is among the main individual pollutants usually found in concentrations about 20 μg L^{-1}. Chemical formula of acetaminophen is shown in Figure 1.

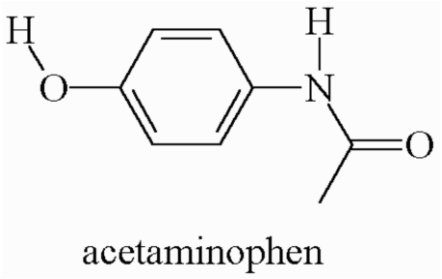

Figure 1. Acetaminophen

Ibuprofen is an optically active compound. Ibuprofen is found in some water resources and is toxic for human, flora and funa. These compounds are persistent during the treatment process of drinking water. Chemical formula of ibuprofen is shown in Figure 2. The objective of this study is to evaluate the concentration of acetaminophen and ibuprofen in untreated

Materials and Methods

Study area

Latyan Dam on the Jajrood river is used for drinking water supply in Tehran (Figure 3). About 30% of drinking water of Tehran is supplied by this dam. Latyan dam lake is used for drinking water supply of east part of Tehran (Figure 4).

Figure 3. Map of Latyan area

Acetaminophen and ibuprofen concentrations

Five sampling stations in this area were selected (Figure 5). These stations located in springs, river, Dam lake and one station after treatment facilities. All the samples were gathered in summer 2016 in randomized design. To avoid the effect of light, samples were gathered in dark sterile bottles. All the samples were analyzed for acetaminophen and ibuprofen concentrations in μg L^{-1} using High Performance Liquid Chromatography (HPLC). This is a separation technique that relies on relative motion of two phases. In liquid chromatography, motion phase is liquid. In gas chromatography, motion phase is gas. Extraction is the first step. For this purpose an appropriate solvent is added to desired material. In this study, liquid-liquid extraction is used. Because the solvent used for separation of acetaminophen and ibuprofen was liquid. The solvent used must have the following two characteristics: a) analyte should not solve in it and the solvent do not solve in matrix. The portion of solvent to sample was 1 to 10. The prepared sample is placed inside the mixer. Until water and solvent completely be mixed with each other. Then analyte be extracted. In the next step, material is placed in the decanter's funnel. Using the end valve, desired section is separated and considered. When analyte is injected into the device, chromatogram indicator is generated and identified by detector. To determine the concentration of acetaminophen and ibuprofen in extract solvent, first a 100% acetaminophen and ibuprofen solvent is prepared (CRM). Then CRM is injected. After that a graph with a specific level and pic is produced. Then analyte is injected and again a specific graph is produced. Two graph with one pic are compared. After obtaining desired pic, they are compared with CRM pic and then concentrations of acetaminophen and ibuprofen are determined.

Statistical analyses

All the experiments were performed in triplicate and the statistical analysis was performed using SPSS software package. To approve the variability of results, all the data were subjected to analysis of variance to consider the significance differences. Furthermore means comparison between data was obtain using Duncan test.

Results

Concentrations of acetaminophen and ibuprofen (ηg L^{-1}) in drinking water supply of east part of Tehran is shown in Table 1. Moreover ANOVA analyses of acetaminophen and ibuprofen concentration data is shown in Table 2.

Table 1. Concentrations of Acetaminophen and Ibuprofen in ηg L^{-1} in drinking water supply of east part of Tehran. All data are mean of three replicate ± SD. (LOD: limit of detection; nd: not detectable). P<0.05. There is no significant differences between data

	Station 1 After treatment facilities	Station 2 Dam Lake	Station 3 Rasnan Spring	Station 4 Jajrood river	Station 5 Afjeh spring
Acetaminophen	nd	9.17 ± 0.18	< LOD	2.16 ± 0.09	< LOD
Iboprufen	nd	11.49 ± 0.33	< LOD	< LOD	< LOD

	Sum of Squares	df	Mean Square	F	Sig.
Acetaminophen	189.378	4	47.345	5587.4	0.000
Ibuprofen	317.216	4	79.30	3577.6	0.000

Discussion

During last two decades, globally increasing consumption of chemicals compounds and detection of emerging contaminants in aquatic ecosystems from ng L^{-1} to lower µg L^{-1} gained much attention (Gabarrón, Gernjak, Valero, Barceló, Petrovic & Rodríguez-Roda 2017). Trace concentrations of pharmaceutical compounds have been detected in groundwater, surface water and drinking water (Bruce, Pleus & Snyder (2010); Fram & Belitz, (2011)). Among all emerging contaminants in raw water, pharmaceutical products and residues are of great important. (Mompelat *et al.* 2009). There are no regulation for drinking water including acetaminophen and ibuprofen removal, assessing this products in water has significant role in reduction of human health risks. Degradation of acetaminophen with initial concentration of 100 µg L^{-1} was considered in a study carried by (Klamerth, Rizzo, Malato, Maldonado, Agüera & Fernández-Alba 2010). Degradation rate is totally independent of pH, the initial H_2O_2 concentration and also the type of acid used for release of hydroxyl radicals scavengers. This study showed that degradation of acetaminophen in waste water led to toxicity increase (Klamerth *et al*. 2010). Moreover Vergili (2013) has found the presence of ibuprofen in drinking water resources. In the study carried out by Luque-Espinar *et al*. (2015) ibuprofen was detected

several times with concentration ranges from 5.3 to 20.8 μg L^{-1}. In the present study acetaminophen concentration in Latyan Dam Lake was 9.17 ± 0.18 ηg L^{1}. And in the case of ibuprofen the concentration was equal to 11.49 ± 0.33. No presence of acetaminophen and ibuprofen was detected in drinking water samples gathered after treatment facilities. There was no correlation between acetaminophen concentration in the source water and in the drinking water over the one year study period. Pharmaceuticals were known as indicators for controlling the quality of raw water and the treatment efficiency in the drinking water treatment facilities (Gaffney, Almeida, Rodrigues, Ferreira, Benoliel & Vale Cardoso 2015). As a result, ground water of this area are sate with no detection of acetaminophen and ibuprofen.

چکیده

بروز آلودگی‌های نوظهور آب آشامیدنی، در دولت، افکار عمومی و تأمین‌کنندگان آب آشامیدنی ایجاد نگرانی نموده است. بروز ترکیبات دارویی در آب و غذا برای سلامتی انسان ایجاد ریسک می‌نماید. استامینوفن و ایبوپروفن جزء سری داروهایی هستند که در سطح جهانی، زیاد تجویز می‌شوند. در این مطالعه آب خام و آب آشامیدنی منطقه سد لتیان از نظر وجود استامینوفن و ایبوپروفن مورد بررسی قرار گرفته است. سپس داده‌های مورد آنالیز واریانس و تفاوت معناداری قرار گرفته و با استفاده از تست دانکن مورد مقایسه میانگین قرار گرفته است. نتایج حاصله نشان داد که استامینوفن در منابع آب زیرزمینی وجود ندارد. اما در رودخانه جاجرود و دریاچه سد لتیان غلظت استامینوفن به ترتیب ۰/۰۹ ± ۲/۱۶ و ۰/۱۸ ± ۹/۱۷ نانوگرم بر لیتر گزارش شده است. در مورد ایبوپروفن تنها غلظت مشاهده شده ۰/۳۳ ± ۱۱/۴۹ نانوگرم بر لیتر بوده در حوضچه سد لتیان است. بعد از عملیات تصفیه آب آشامیدنی، استامینوفن و ایبوپروفن در نمونه‌های جمع‌آوری شده مشاهده نشده است. نتایج این تحقیق نشان می‌دهد، چون ترکیبات داروئی شاخص‌های کنترل کیفیت آب خام و تصفیه خانه‌ها محسوب می‌شوند، منابع آب زیرزمینی و آب آشامیدنی تصفیه شده شرق تهران از نظر کیفی نسبت به استامینوفن و ایبوپروفن ایمن محسوب می‌شوند.

کلمات کلیدی: آب خام، استامینوفن، ایبوپروفن، آلودگی.
